If you use World Wide Web more or less often, you must have already come across with spyware. You may not even know about it or haven't noticed your computer being infected with dozens of spyware components, but the fact is that almost 100% of computers know how does it feel like to have a spyware inside. This article is all about getting rid of these unwanted pieces of software and about different methods of doing that.

First of all, you should know (or, at least, guess) if your PC is infected. There can be different signs of this, and the most common ones are: computer works slower than usual, different annoying things appear on your desktop or browser panels (e.g. toolbars, icons), PC starts working strangely (irregular short slowdowns start taking place). If you see that something wrong is with your machine, probably there is a spyware.

How to get rid of spyware? There are different ways of doing that, but an absolute favorite is removing it with the help of antispyware. There can be nothing easier than that – simply install one of the dozens different programs, available on the Internet (you may use free trial versions in order to evaluate products and decide which is the most suitable choice). Right after that, download the newest update pack (this may sound as a complicated task, but in reality it is very simple and doesn't require much time or efforts). If you have installed the latest update (without it your antispyware program would not be able to detect newest threats), all you will have to do is starting a scan procedure and your program will do the rest of the job automatically! The last step, which could require your attention, is dealing with a list of detected pests (don't be scared if it is really long) – you may not check several components, which looks like spyware but in reality they are important system parts. So, the job is done and you may start enjoying your PC again!

Another way of removing spyware is more complicated and requires more knowledge. It is called “manual removing” and is being used when antispyware cannot help (this may happen when a specific parasite had left traces, such as junk files or registry entries). The majority of antispyware sites offer thousands of manual removal instructions: all you have to do is finding the one you need and follow steps, described in there. Sometimes these steps includes instructions about removing registry entries, so make sure you know how to delete, modify or add these into your system's registry.

All in all, as you see, removing spyware is not as hard as it may seem to be from the first glance. Modern antispymware systems are really easy to use and effective, that's why you will experience no problems with the majority of parasites. In case your security system is unable to deal with specific parasites, you may always remove them manually (it is recommended to back up your system before doing that) and feel what it's like to have a quick and "healthy" computer!
