If you started reading this article, you probably don't know what in general spyware is. If you still need a definition, spyware is a kind of malicious program, which don't specialize in destroying vitally important components of the infected system, but in spying (mining private data, harvesting for specific information, etc.).

Even if you know WHAT spyware is, you may ask: WHY should you remove it? Well, it doesn't damage your PC, makes no visible difficulties for your work... What is wrong about the fact that several silent and harmless programs are running in background and performing needless actions? You know, many users think in this way, but they are strongly mistaken, because spyware can become a reason of serious damage, especially in security areas.

Do you need examples? Here they are! There is a small, "harmless" utility installed on your computer. You use it quite often and find it useful (no matter what it does – it may be a simple calculator or system doctor), but it also has the ability of spying you. Without letting you know about its secret activities, this program regularly searches for special (sometimes private) information and sends it to its owner. Sometimes this stolen information is useless, but often it has some value – for example, it may let its creator know what are you doing with the help of your computer, which places on the Internet do you visit, which programs are installed on your PC, etc. Do you think there is absolutely nothing dangerous and suspicious about somebody knowing what you do and what private information you possess? If so, you may continue thinking spyware is absolutely harmless and no actions against it should be taken.

Here is one more really important aspect of the problem. Spyware usually gets installed on the victim's PC silently, that's why sometimes this procedure makes it quite hard for your system to work in a stable way. As a result of this, various system troubles (such as slowdown or the loss of performance) occurs and you find it quite hard to use a computer, which is full of spyware. In our opinion, this fact is a strong advantage of removing spyware from your computer and "ruining all bridges", so spyware would never be able to come back.

In conclusion, we would like to repeat once again – we strongly believe that removing spyware from your

PC is a great benefit for you and the whole system. Nowadays, removing spyware is as easy as never before – all you need is downloading and starting special software, which would do all the hard job, leaving you an option to choose which components to delete and which should stay on your hard disk. If you are really concerned about having your PC quick and clean, we recommend thinking about this problem and taking steps we have already described.
